Pointer and Array

Recall the relation between pointer and array name

Pointers and array names **seem** to be same!

YES, they are almost the same except that
the value of array names cannot be modified,
but the one of pointers can!

A string constant

```
1 "Hello world"
2 "Good morning"
3 "Zhang San"
4 "2017-12-11"
```

A string is essentially an array of characters!

When you call `printf("Hello world");`, the **beginning address** of the array storing "Hello world" is passed to `printf`.

```
1 char hw[]="Hello world"; // declare an array storing the string
2 char *hw="Hello world"; // declare a character pointer storing the beginning address of the array
   storing the string.
```

Character pointer as function argument

Recall the exercise:

getInt,

传过来的字符数组

结果保存在 num 里。

```
1 void getInt(char * str, int *nums){  
2     while(*str!='\0'){ // check if the string reaches the end ]  
3         if(*str>='0'&&*str<='9'){  
4             *nums=*str-'0'; // store the current number to the integer array  
5             nums++; // move to next empty cell in the integer array  
6         }  
7         str++; // move to the next character  
8     }  
9 }
```

Pointer array (指针数组)

`type *ptrs[N];` // define N pointers as an array (保存了 N 个指针变量)

`ptrs` is the array name

```
1 char* names[4]={"Zhang San", "Li Si", "Wang Wu", "Zhao Liu"};  
2 for(i=0;i<4;i++)  
3   printf("%s",names[i]); // or *(names+i)
```

Exercise: sort the strings and print them out in lexical order

Multi-dimensional arrays

Back to the previous example:

```
1 char* names[4]={"Zhang San", "Li Si", "Wang Wu", "Zhao Liu"};
```

Remember that: each string is an **array**. There are **four** arrays
The four arrays compose an **array**, which is called *array of arrays*, that is, **two-dimensional array**.

```
1 char names[4][10]={"Zhang San", "Li Si", "Wang Wu", "Zhao Liu"};
```

Another example:

```
1 int dates[2][13]={  
2     {0, 31, 28, 31, 30, 31, 30, 31, 31, 30, 31, 30, 31},  
3     {0, 31, 29, 31, 30, 31, 30, 31, 31, 30, 31, 30, 31}  
4 };
```

Usage: `dates[i][j]`: the j^{th} element in the i^{th} array.

The essence of two-dimensional array

We know that **an 1-d array name is essentially a pointer.**

```
1 int dates[2][13]={  
2     {0, 31, 28, 31, 30, 31, 30, 31, 31, 30, 31, 30, 31},  
3     {0, 31, 29, 31, 30, 31, 30, 31, 31, 30, 31, 30, 31}  
4 };
```

E.G. `dates[0]` is a pointer, `dates[1]` is a pointer.

Thus, **the array name of a 2-d array is a pointer, pointing to the first address of the first 1-d array.**

Declaration of a pointer to pointers

```
type **ptr;
```

Remember: `ptr` points to a location storing a pointer.

Recall the definition of Pointer

Pointer

A pointer is a **variable** that contains the **address** of some variable.

| | | | | | | | | | |
|---|---|---|---|---|---|---|---|--------------------|---------------|
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0x0000000000000000 | short int a; |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0x0000000000000001 | a=1; |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0x0000000000000002 | short int *b; |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0x0000000000000003 | b=&a; |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0x0000000000000004 | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0x0000000000000005 | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0x0000000000000006 | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0x0000000000000007 | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0x0000000000000008 | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0x0000000000000009 | |

Definition of Pointer to pointers

Pointer

A pointer to pointers is a **variable** that contains the **address** of some **pointer(s)**.

| | | | | | | | | | |
|---|---|---|---|---|---|---|---|--------------------|----------------|
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0x0000000000000000 | short int a; |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0x0000000000000001 | a=1; |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0x0000000000000002 | short int *b; |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0x0000000000000003 | b=&a; |
| . | . | . | . | . | . | . | . | ... | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0x0000000000000005 | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0x0000000000000009 | |
| 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0x000000000000000A | short int **c; |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0x000000000000000B | c=&b; |
| . | . | . | . | . | . | . | . | ... | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0x0000000000000011 | |

What do we use pointer to pointers

Pointer to pointers and 2-d arrays are good friends!

```
1 char names[4][10]={"Zhang San", "Li Si", "Wang Wu", "Zhao Liu"};
2 char *ptr[4]; // declare a pointer array
3 int i;
4 for(i=0;i<4;i++){
5     ptr[i]=names[i]; // let ptr point to names
6     printf("%s\n",*(ptr+i)); // or ptr[i], remember ptr[i] is a pointer
7 }
```

Now that `ptr` is the almost the same as `names`, why don't we just use `names` directly? Consider the following problem:

String sorting

Define a function which sorts the names in `names`.

What do we do?

Before sorting

names[0] → "Zhang San"
names[1] → "Li Si"
names[2] → "Wang Wu"
names[3] → "Zhao Liu"

After sorting

names[0] → "Li Si"
names[1] → "Wang Wu"
names[2] → "Zhang San"
names[3] → "Zhao Liu"

copying string is expensive!

Before sorting

ptr[0] → names[0] → "Zhang San"
ptr[1] → names[1] → "Li Si"
ptr[2] → names[2] → "Wang Wu"
ptr[3] → names[3] → "Zhao Liu"

After sorting

~~ptr[0] → names[0] → "Zhang San"~~
~~ptr[1] → names[1] → "Li Si"~~
~~ptr[2] → names[2] → "Wang Wu"~~
ptr[3] → names[3] → "Zhao Liu"

Not necessary to copy string!

Code

```
1 char names[4][10]={"Zhang San", "Li Si", "Wang Wu", "Zhao Liu"};
2 char *ptr[4]; // declare a pointer array
3 int i,j;
4 for(i=0;i<4;i++){ptr[i]=names[i];} // let ptr point to names
5 char *tmpPtr;
6 for(i=0;i<4;i++){
7     for(j=i+1;j<4;j++){
8         if(strcmp(ptr[i],ptr[j])>0){
9             tmpPtr=ptr[i]; ptr[i]=ptr[j]; ptr[j]=tmpPtr;}
10    }
11 }
12 for(i=0;i<4;i++){
13     printf("%s\n",*(ptr+i));} // or ptr[i], remember ptr[i] is a pointer
```

What happens inside

(1)

| | | | |
|--------|---|----------|-------------|
| ptr[0] | → | names[0] | "Zhang San" |
| ptr[1] | → | names[1] | "Li Si" |
| ptr[2] | → | names[2] | "Wang Wu" |
| ptr[3] | → | names[3] | "Zhao Liu" |

(3)

| | | | |
|--------|---|----------|-------------|
| ptr[0] | ✗ | names[0] | "Zhang San" |
| ptr[1] | ✗ | names[1] | "Li Si" |
| ptr[2] | | names[2] | "Wang Wu" |
| ptr[3] | | names[3] | "Zhao Liu" |

| | | | |
|--------|---|----------|-------------|
| ptr[0] | ↗ | names[0] | "Zhang San" |
| ptr[1] | ↘ | names[1] | "Li Si" |
| ptr[2] | ↘ | names[2] | "Wang Wu" |
| ptr[3] | → | names[3] | "Zhao Liu" |

(2)

| | | | |
|--------|---|----------|--------------------|
| ptr[0] | ✗ | names[0] | <u>"Zhang San"</u> |
| ptr[1] | ✗ | names[1] | <u>"Li Si"</u> |
| ptr[2] | → | names[2] | "Wang Wu" |
| ptr[3] | → | names[3] | "Zhao Liu" |

| | | | |
|--------|---|----------|-------------|
| ptr[0] | ↗ | names[0] | "Zhang San" |
| ptr[1] | ↘ | names[1] | "Li Si" |
| ptr[2] | ↘ | names[2] | "Wang Wu" |
| ptr[3] | | names[3] | "Zhao Liu" |

| | | | |
|--------|---|----------|-------------|
| ptr[0] | ↗ | names[0] | "Zhang San" |
| ptr[1] | ↘ | names[1] | "Li Si" |
| ptr[2] | ↘ | names[2] | "Wang Wu" |
| ptr[3] | → | names[3] | "Zhao Liu" |

Another problem

Write a function for string sorting!

```
1 char names[4][10]={"Zhang San", "Li Si", "Wang Wu", "Zhao Liu"};
2 char *ptr[4]; // declare a pointer array
3 int i,j;
4 for(i=0;i<4;i++){ptr[i]=names[i];} // let ptr point to names
5 char *tmpPtr;
6 for(i=0;i<4;i++){
7     for(j=i+1;j<4;j++){
8         if(strcmp(ptr[i],ptr[j])>0){
9             tmpPtr=ptr[i]; ptr[i]=ptr[j]; ptr[j]=tmpPtr;}}}
10 for(i=0;i<4;i++){
11     printf("%s\n",*(ptr+i));} // or ptr[i], remember ptr[i] is a pointer
```

Another problem

Write a function for string sorting!

```
1 void sortString(char *str[], int n){ // notice the parameter *ptr[]
2     char *tmpPtr;
3     int i,j;
4     for(i=0;i<n;i++){
5         for(j=i+1;j<n;j++){
6             if(strcmp(str[i],str[j])>0){
7                 tmpPtr=str[i]; str[i]=str[j]; str[j]=tmpPtr;}}
8     }
9
10 sortString(ptr,4); // the way of calling the function
```

2-d array as function argument

The following declarations are equivalent. The first argument should be a 2-d array. **The first value in the array is ignored by compilers**

- 1 `void sortString(char str[4][10], int n)`
- 2 `void sortString(char str[][10], int n)`
- 3 `void sortString(char (*str)[10], int n)`

It is **different from**: `void sortString(char *str[10], int n)`
Because **[] has a higher precedence than ***
`char *str[10]` is a pointer arrays.

Because numbers in array is **free**, the above declaration is equivalent to:
`void sortString(char *str[], int n)`, or
`void sortString(char **str, int n)`

Differences (cont.)

1 void sortString1(char str[][10], int n)

The first argument should be an array name of a 2-d array

```
1 char strs[2][10]={"abc","def"};
2 sortString1(strs, 2); // call sorting
3 char **ppstr=strs; //bad
4 char *pstr=&strs[0][0];
5 sortString1(ppstr,2);//bad too
```

2 void sortString2(char **str, int n)

The first argument should be a pointer (or an array name) to a pointer array

```
1 char *strs1[10]={"abc","def"};
2 sortString2(strs1, 2); // call sorting
3 char **ppstr=strs1; //good
4 sortString2(ppstr, 2); //good
5 sortString2(strs,2) // bad
```

Differences between pointer to pointers and 2-d array name

指针

```
1 char name[]="Zhang San";  
2 char *pname=name;
```

```
1 char *names[4];  
2 (char *)*pnames=names;
```

= 二维数组

```
1 char name[][20]=  
2 {"Zhang San","Li Si"};  
3 char *pname=name[0]; //OK  
4 char *pname=name; // bad  
5 printf("%s",name[1]);  
6 printf("%s",pname+20);
```

二维数组地址

pointer to pointers

双重指针

一个指针，保存了另外一个指针变量的地址。

- A 2-d array is a pointer with length information. The length is the size of the types of each 1-d array.
- A pointer to pointers is a pointer with length being 8, which is the size of address

Arguments of programs

→ 指针数组

```
1 int main(int argc, char *argv[]){  
2     int i=0;  
3     while(i<argc){  
4         printf("%s\n",argv[i++]);  
5     }  
6     return 0;  
7 }
```

- argc: the number of arguments (including the command)
- argv: a pointer array with each pointing to a string in the arguments.

Exercise

Write a program named `convert` to convert its arguments into low-case or upper-case according to its option

- Command: `convert -l ABC`
Result: `abc`
- Command: `convert -u abc`
Result: `ABC`
